Acronyms and Abbreviations

Blank	quality assurance sample composed of deionized water
°C	temperature in degrees Centigrade
Duplicate	quality assurance sample replicate
EC	electrical conductivity normalized to 25 °C
GW	ground water
HDPE	high-density polyethylene
µg/L	micrograms per liter
mg/L	milligrams per liter
QA	quality assurance
QAPP	Quality Assurance Project Plan
QC	quality control
Reclamation	United States Bureau of Reclamation
Ref	quality assurance sample composed of reference material of a known concentration
RL	reporting limit
SJR	San Joaquin River
SOP	standard operating procedure
Spike	quality assurance sample composed of environmental sample-water with added constituent(s) of known concentration(s)
SW	surface water
WQ	water quality

Introduction

The Water Quality Monitoring Study for Seepage Management Projects (Study) is a multi-year water quality monitoring study conducted by the US Bureau of Reclamation (Reclamation) with the primary goal of helping to determine how increased flows within the San Joaquin River (SJR) might affect the quality of ground water (GW) within adjacent lands. Study data is being used secondarily to help evaluate whether SJR seepage-water could be released to local irrigation canals without degrading existing canal water quality (WQ).

Data presented in this report was collected March 2017. These data reflect the quality of SJR surface water (SW), and SJR seepage GW, during a period of high SJR flow. Samples were collected during the wettest year in California since record keeping began (1895); at the time of sample collection, the river had been at flood stage for over a month. Data from previous monitoring events (December 2012, May 2013, and August 2015), was collected under significantly-lower SJR flow conditions.

Methods

Target analytes, analytical methods, quality assurance (QA) methods, and sample collection methods for the 2017 sampling event are identical to those used in previous Study events, with one exception. In 2012 and 2013, metals, calcium, magnesium, and boron concentrations were analyzed as “totals” (sample water was not filtered prior to analysis), while in 2015 and 2017, these analytes were analyzed as “dissolved” (water was filtered prior to analysis). Total concentrations, which capture both ionic and particulate concentrations, were initially measured because for some analytes, WQ standards were only available for total analyses, in addition, many irrigation suitability limits are based on total analyte concentrations. In 2015 and 2017, dissolved concentrations were analyzed in order to better evaluate WQ for the protection of fish and wildlife; in particular, aquatic organisms, are primarily exposed only to dissolved analytes.

QA and field methods are described in detail in previous Study reports (Reclamation, 2012a; Reclamation, 2013, Reclamation, 2015) and in the current Quality Assurance Project Plan (QAPP) for the Study (Reclamation, 2016). Analytical methods are described in published and widely accepted analytical methods documents and are available by request from Reclamation QA staff. A general overview of sampling and QA methods is given below.

Site Locations and Schedule

Ground water samples were collected March 13, 14, and 15, 2017; surface water samples were collected March 21 and March 22, 2017. Sample collection information is summarized in Table 1 (sample identification codes, sampling dates, and site locations).

Sample Collection and Storage

Field procedures were performed following Branch of Environmental Monitoring standard operating procedures (SOPs) for sample collection, handling and documentation. Step-by-step descriptions of these procedures (Reclamation, 2012b) are summarized below.

In order to minimize the potential for environmental contamination, and to minimize cross-contamination between samples, disposable materials were used when possible. Disposable sampling materials (e.g. nitrile gloves, sample containers, bailers, bailing twine) were selected new for each sample collected. Non-disposable equipment (e.g. Sonde, sample churn splitter, water level meter) was cleaned prior to each use. Items were cleaned using concentrated residue-free detergent (Liquinox®) diluted with de-ionized water, then triple rinsed with de-ionized water, and triple rinsed again, with environmental (site) water.

Surface water grab samples were collected using a clean, high-density polyethylene (HDPE) churn splitter, then dispensed from churn to sample bottles. Ground water was collected using two new HDPE bailers and new braided nylon twine for each well. Prior to GW collection, water-column height was determined, then at least three well-volumes of water were purged using one of the two new bailers designated for that well. When bailing, to prevent suspending potential accumulated sediment, care was taken to avoid hitting the bottom of the well. After purging, the second new bailer was used for sample collection. For most GW samples, water was dispensed directly from bailer to sample bottle. Duplicate and triplicate samples (used for QA purposes) were poured from bailer to a clean churn splitter, then dispensed into sample bottles following standard protocols for achieving replicate samples (Reclamation, 2017).

Sample bottles were kept cool and out of direct sunlight both prior to and during sample collection. Within five minutes of being filled, sample containers were placed in coolers packed with blue ice and stored in the shade. While samples were in the field, blue ice packs were tested for firmness at least every two hours; ice packs did not appear to soften significantly during use. Samples were stored in coolers for up to eight hours prior to arriving at the commercial analytical laboratory (organics), or to the Reclamation QA laboratory (inorganics). At the laboratories, samples were refrigerated and stored at approximately 4 °C.

Following completion of Reclamation QA procedures, inorganic samples were shipped via commercial courier (FedEx) from the Reclamation QA laboratory to the commercial analytical laboratory. Shipments were arranged for next-day delivery and samples were stored on blue ice during transport.

Sample volumes, container materials, chemical preservatives, and sample hold-times¹ are specified in analytical methods documents. Container, preservation and other method requirements were met for all samples.

Chemical Analyses

Chemical analyses were performed by commercial analytical laboratories in accordance with the analytical methods documents published for each method. Methods documents are available on-line and by request from Reclamation QA personnel. Specific methods used for each analysis are shown in analytical results summary tables (Table 2 –inorganic analytes and physical measurements, Table 3 – undetected organic chemicals, and Table 4 – detected organic chemicals). When possible, selected methods were chosen to yield reporting limits (RLs) three to five times lower than the lowest applicable water quality limit. Note that due to matrix affects and other sample-specific analytical complexities, achieved RLs did not always match method reporting limits. For similar reasons, RLs sometime differ between samples that were analyzed for the same constituent.

Water Quality Objectives and Limits

WQ Objectives (also termed “protections”) and numeric limits and criteria (for simplicity termed “limits” in this report) were chosen for the protection of fish and wildlife habit, irrigation, and watershed-specific concerns (Table 5).

To evaluate WQ for use by fish and wildlife, WQ objectives and numeric limits were drawn from the California State Water Resources Control Board (SWRCB) publication, “A Compilation of Water Quality Goals” (Marshack, 2017), which by reference also includes Ayers and Westcott (1985). Specific fish and wildlife protections do not exist, so objectives were selected for the protection of Fresh Water Aquatic Life (FWAL) and Poultry and Livestock (P&L).

- FWAL objectives are evaluated here through sub-objectives: the California and National Toxics Rules (CTR/NTR) and the National Recommended Water Quality Criteria (NRWQC). Non-binding NRWQC limits were used in cases where additional CTR/NRT limits do not exist. If both CTR/NTR and NRWQC limits exist for a single analyte, WQ was evaluated using the legally binding Toxics Rules.
- P&L limits are defined as “Agricultural Limits” by Marshack, but are used in this Study to evaluate water suitability for consumption by non-aquatic wildlife (birds and mammals).

WQ limits for the evaluation of irrigation suitability (IRRIG) were selected from Ayers and Westcott, 1985.

¹ Samples must be extracted or analyzed within the method-specified “hold time” (usually stated as hours, days or weeks) to ensure that chemical concentrations detected in the laboratory are representative of concentrations under field conditions.

Water Quality Monitoring for SJR Seepage Management

Limits for the protection of location-specific concerns (BP) were selected from the Water Quality Control Plan (Basin Plan) for the Sacramento and San Joaquin River Basins (SWRCB, 2017).

Consistent with Reclamation standard practice, to evaluate both FWAL and BP objectives, SW standards were used to evaluate GW quality. This practice is appropriate because current GW objectives are narrative, stating that GW, “shall not contain chemical constituents in concentrations that adversely affect beneficial uses” and that GW “shall be maintained free of toxic substances in concentrations that produce detrimental physiological responses in human, plant, animal or aquatic life associated with designated beneficial use(s)” (SWRCB, 2017). These narrative standards cannot be evaluated quantitatively. SW standards are applicable for evaluating GW because once the water is pumped to the surface, it becomes available *as SW*. It should be noted however, that GW “objectives do not require improvement over naturally occurring background concentrations” and the objectives “are not required by the federal Clean Water Act.”

WQ is evaluated in this study by comparing analyte concentrations (results) with WQ limits that are applicable to relevant WQ objectives (e.g. IRRIG). If an analyte concentration is within the limits established for the stated WQ objective, the water “meets” WQ standards for that water use. Note that IRRIG limits unlike other WQ limits, which are meant to be fully protective of a certain water use, IRRIG limits can be nuanced and indicate restrictions on water use. For example, water with a certain sodium chloride concentration may be more suited to drip irrigation than to overhead sprinkling, or may be restricted to certain application rates in order to avoid leaf-burn in particular crops. For more information on the use-restrictions associated with particular analytes, see Ayers and Westcott, 1985.

Quality Assurance

The quality of the data presented in this report was evaluated through the commercial laboratory’s quality control (QC) system, and through Reclamation’s independent quality management system (QMS). Reclamation’s QMS increases confidence in data validity and legal defensibility and is summarized as follows.

- QA audits are conducted on-site to verify that field and laboratory procedures are consistent with stated SOPs.
- Reclamation “QA samples” (e.g. duplicates, blanks) are submitted “blind” (without identification) to the analytical laboratories alongside study samples in order to evaluate sample results for potential issues with precision, accuracy, and contamination.
- Commercial laboratory QA/QC reports are reviewed by Reclamation QA staff who highlight any potential data issues
- Analytical results that do not meet Reclamation QA acceptance criteria are flagged with an alpha code indicating possible data issues (e.g. a result flagged as “potentially biased low” is followed by an “L”)

Results and WQ Evaluation

Inorganic Chemicals and Physical Measurements

Results of inorganic analyses and physical measurements are shown in Table 2.

Surface Water

Five inorganic analytes (alkalinity, boron, copper, lead, and nickel) failed to meet one or more applicable WQ objectives in at least one of the three surface water samples collected.

- IRRIG limits for boron were exceeded in all surface water samples. Note that this boron limit is designed for unfiltered samples, but is applied here to filtered samples. Boron concentrations are likely lower in dissolved than in total samples.
- FWAL limits were exceeded at all surface water sites for copper. FWAL limits were also exceeded for lead, nickel, and alkalinity in water collected at the Bifurcation Structure. Due to insufficiently low reporting limits, FWAL limits couldn't be evaluated for lead at Sack Dam or Highway 152 and zinc couldn't be evaluated at any of the three sites.
- BP limits for boron were exceeded in samples collected at Sack Dam and Highway 152.

Ground Water

In ground water samples (16 wells total), eight conventional analytes (bicarbonate, boron, chloride, EC, nitrate, sodium, SAR, and TDS) and five metals (aluminum, copper, lead, selenium, and zinc) were commonly present in concentrations exceeding limits for the protection of one or more WQ objectives.

IRRIG limits were typically exceeded for boron and chloride (16/16 and 15/16 wells respectively); commonly exceeded for bicarbonate (7/16), EC (9/16), sodium (9/16), SAR (7/16) and TDS (8/16); and less commonly exceeded for nitrate (3/16). As noted above, the IRRIG boron limit is designed for unfiltered samples, but is applied here to filtered samples. Boron concentrations are likely lower in filtered than in total samples.

Water Quality Monitoring for SJR Seepage Management

FWAL limits were exceeded for chloride in water collected at four wells: MW-11-157, MW-12-169, MW-13-213 and MW-14-205. FWAL limits were also exceeded for aluminum, copper, lead, and zinc, as indicated below.

MW-12-185: copper

MW-12-187: copper, lead, zinc

MW-13-210: copper, lead, aluminum

MW-14-206: aluminum

The FWAL limit for aluminum is based on unfiltered water but is applied here to filtered samples. Aluminum concentrations are likely to be lower in filtered than in unfiltered samples.

Organic Chemicals

Most organic constituents that were analyzed in this study were not detected (42 detections in approximately 2700 analyses) and no organic chemicals were detected in surface water samples. Organic constituents that were not detected are listed in Table 3.

Organic chemicals (organics) were detected in water collected at six well sites (Table 4). Most organics were detected in water collected from MW-11-150 and this well contained 16 chemicals in concentrations exceeding applicable WQ limits (34 total organics detected; seven exceed BP limits, nine exceed FWAL limits). Organics were also present in concentrations exceeding applicable WQ limits in water collected at MW-11-157 (three organics detected, all exceed BP limits).

Organic chemicals were also detected in water collected at four additional wells (MW-11-150: five detections; MW-12-178: two detections; MW-13-213 and MW-14-205: one detection each). None of these detections exceeded WQ limits.

Semi-volatile organics results for MW-14-208 were not evaluated due to laboratory error.
