

San Joaquin River Restoration Program, 2013 Chinook Salmon Trap and Haul Summary

Introduction

The Hills Ferry Barrier (HFB) is constructed annually by California Department of Fish and Wildlife (CADFW) to prevent upstream movement of fall-run Chinook salmon in the San Joaquin River (SJR) beyond the confluence with the Merced River. Upstream of this confluence, the SJR does not provide access to suitable spawning habitat for adult salmon because upstream obstacles prevent passage (*e.g.* dry river sections, Sack Dam, Mendota Dam). Furthermore, return flows from Salt and Mud Slough often attract salmon into irrigation canals that provide no spawning habitat nor return access to the river. However, even with the HFB in place, some salmon are able to circumvent the barrier. Because fish passing this point would otherwise be lost in the system, it provides an opportunity to translocate fall-run Chinook salmon to study their behavior and spawning site preference prior to reintroduction. During the 2013 Trap and Haul, from October 1 – December 15, 2013, Reclamation personnel captured Chinook salmon using fyke nets in the mainstem SJR, Mud and Salt Slough, and near the confluence of the SJR with the Eastside Bypass, and CADFW personnel captured salmon using dip nets at the terminal end of irrigation canals upstream of the HFB. Once captured, these fish were transported upstream to suitable spawning habitat in Reach 1 of the Restoration Area. While the majority of fish were released back into the SJR, some fish were retained for artificial spawning and incubation purposes.

Methods

Location, capture, and transport

Reclamation personnel captured salmon using fyke nets at five locations: immediately above the HFB, approximately 0.6 river miles upstream of the barrier (Casey property), Mud Slough, Salt Slough, and near the confluence of the Eastside Bypass and the SJR (near Van Clief Rd.). The two downstream-most fyke nets were placed in the river with wing walls extending towards each bank, leaving approximately 3 – 5 m open on one side for boat passage. The remaining three fyke nets were placed in each respective location with wing walls extending from the main net to the bank on either side. In some instances, a small gap (< 1

m) was left between the bank and the end of the wing wall to permit local wildlife (*i.e.* beavers and muskrat) to pass around the net. In instances where such wildlife entered the net, resulting damage to the net was sustained when the netting was chewed, precluding fish capture. Each fyke net was checked for fish daily, debris removed, and relocated a few meters up- or downstream depending on the amount of riverbed scouring (Figure 1).

Figure 1.–Daily cleaning and reset of Salt Slough fyke net.

California Department of Fish and Wildlife personnel captured salmon at the terminal end of irrigation canals using dip nets at six locations near Los Banos, CA: Delta Rd., Midway Rd., Hereford Rd., Deepwell Rd., Britto Rd., and Cozzi Ave.

A fin-clip was taken from each salmon captured for DNA analysis. Fish were sexed (males checked for presence of milt/females determined to be gravid or not), tagged (see “Tagging methods”), measured (nearest mm, fork and total length), checked for the presence of an adipose fin, overall condition recorded, and photographed. Fish were then placed in an oxygenated tank and transported upstream for release in the SJR at Camp Pashayan (river mile 243.2, near State Route 99) or retained for streamside spawning activities.

Tagging methods

All fish captured were tagged using 3.18-cm (1.25-inch) Peterson disc tags (Floy Tag & Mfg., Inc., Seattle, WA). A set of tags were affixed below the dorsal fin rays, on either side of the fish, using a nickel pin inserted through the dorsal musculature (Figure 2). Each disc tag had a unique number and was used to identify fish after release. Three colors were used to mark fish, indicating the

month of capture. Yellow was used in October, green in November, and orange in December. Females were tagged with a solid-color tag. Males were marked with the same color tag, though half the tag was white to help with identification in post-release surveys (Figure 3).

Figure 2.–Salmon displaying Peterson disc tag, being placed into oxygenated transport tank.

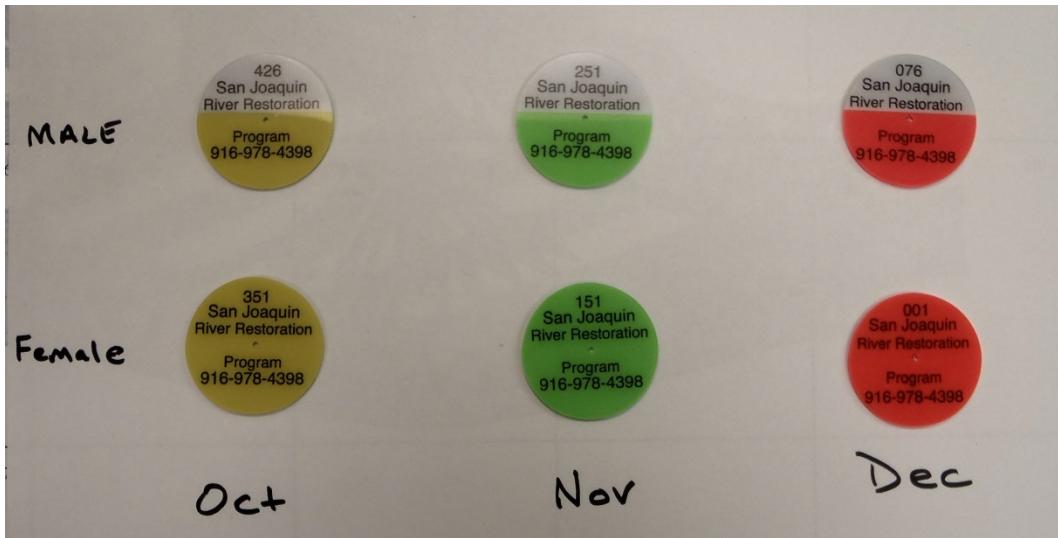

Figure 3.–Peterson disc tags used for identification of salmon by gender and month of capture.

In addition to the disc tags, fifty female salmon were also intragastrically implanted with an acoustic transmitter (V13, 69 kHz transmitter; VEMCO, Bedford, Nova Scotia, Canada), capable of transmitting a unique signal up to 120 days. A bolus gun (often used to dose large pills in livestock), coated in glycerin was used to place the transmitter in the salmon. These tags were used to locate salmon and redds in the river after release in Reach 1.

Results

A total of 367 Chinook salmon were captured between October 1 and December 15, 2013 (Figures 4 – 6). Of the captured fish, 123 (33.5%) were female and 244 (66.5%) were male. The majority of fish (55.3%) were captured during the peak month of November (Figure 4). The ratio of females to males, though, increased from October (26.3%) and peaked in December (66.7%). The majority of fish were captured at the fyke net above Hills Ferry Barrier (33.8%) and with dip nets at the irrigation canal located near Midway Rd. (26.7%). The remaining 39.5% of fish were caught between the other 9 locations (Figure 5). Comparatively, the rate of capture was lower in October and began increasing in early November (Figure 6). Capture rates peaked in mid-November. All efforts concluded December 15, 2013 following removal of the HFB.
